ABSTRACT

Background: Bird is important in maintaining biodiversity and its lifestyles and behaviors will pose an important impact on the ecological environment. Birds are also inseparable for ecological stability. Birds' movement and living habits are a widely studied topic.

Methods: Two economic valuable birds, *Lonchura striata* and *Copsychus saularis*, were selected in this study. It aims at investigating the characteristics of muscle fiber tissues and comparing the differences between male and female species. Histological techniques were used to determine the characteristics of the muscle fiber (diameter, area and density) in leg and pectoral muscles.

Result: There were differences in the muscle fiber characteristics of the *Lonchura striata* and the *Copsychus saularis*. The characteristics of muscle fibers between males and females of the same species were significantly different and there were also significant differences in the same parts of different species. The diameter and area of muscle fibers are correlated to the density of muscle fibers. This study suggested that the characteristics of muscle fibers are related to their living habits and population characteristics.

Key words: *Copsychus saularis*, Histological characteristics, Leg muscles, *Lonchura striata*, Muscle fiber, Pectoral muscles.

INTRODUCTION

Birds involve in the ecosystem and they have complex movements (Debnath *et al.*, 2018). Two common resident birds belonging to Passeriformes, *Lonchura striata* and *Copsychus saularis*, are easy to tame and have certain ornamental value. At present, the research about *Lonchura striata* in China mainly include behavioral studies focusing on nest site selection, breeding, brooding behavior, domestication (Kagawa *et al.*, 2012) and physiological studies on neural system, hormones, embryonic development and so on (Li *et al.*, 1992; Bao *et al.*, 2005; Nottebohm *et al.*, 1990). There are relatively few studies on *Copsychus saularis*, mainly on its feeding, breeding and nesting habits (Barnea *et al.*, 1991) and vocal behavior (Jiang *et al.*, 2003). However, the muscle tissue and molecular ecology knowledge of the two birds are lacking. Birds need skeletal muscle to achieve their behaviors and the characteristics of skeletal muscle are associated with the characteristics of muscle fiber tissue. The daily activities of birds are inseparable from pectoral and leg muscle (Torrella *et al.*, 1999). To mind the gap, this study investigated the characteristics of the pectoral muscle and leg muscle, the characteristics of muscle fibers and their influencing factors and the relationship between muscle fibers and movement. It provides basic reference for following muscle and behavioral studies in these two birds.

MATERIALS AND METHODS

The experiment was conducted from 2019-3 to 2020-2 at the Key Laboratory of Southwest China Wildlife Resources Conservation, China West Normal University College of Life Science, Nanchong, Sichuan. 10 adult *Lonchura striata* (5 ♂ 5 ♀) and 10 *Copsychus saularis* (5 ♂ 5 ♀) were collected from Nanchong City, Sichuan, China. For histological observations, the leg and pectoral muscles were

dissected and fixed in 10% paraformaldehyde solution. Fixed tissues were processed with routine paraffin embedding technique for 5 µm paraffin sections. After that, Haematoxylin and Eosin (H.E) staining procedures were performed to show histological changes: Briefly, the slides were treated by xylene dewaxing, ethanol debenzoylation, hydration, washing, hematoxylin staining solution, washing, hydrochloric acid, ammonia water washing, eosin solution restaining, washing, gradient alcohol dehydration and xylene transparency. Then the samples were observed under light microscope (CX50, Olympus, Japan) after sealed with neutral balsam on slides and then take pictures at 400×. Following micrometrical parameters were recorded:

Muscle fiber diameter and area

Using VideoTest-Master Morphology software to measure, the place where the muscle fiber distributed evenly were

chosen and measure the diameter and area of the target muscle fiber.

Measurement of the muscle fiber density

Five intact and clear sites were randomly chosen. The number of muscle fibers at the observed area were then counted for the fiber density size index. The results were shown by the fiber number per square millimeter area.

Data analysis

Data was analyzed by SPSS analysis software 25.0 and excel 365. The experimental samples belong to continuous variables and there is no obvious correlation between the variables. The normality test and the homogeneity test of variance on the samples meet the conditions of the independent sample T test, so the independent sample T test is used. There are many influencing factors in the experiment. In order to further analyze the influence of each factor on the properties of muscle fibers, this experiment also uses univariate analysis of variance to understand the

relationship between each factor. $P < 0.05$ or $P < 0.01$ means the difference is significant or extremely significant.

RESULTS AND DISCUSSION

Histological characteristics of muscle fibers in different parts

The diameter and area of the leg muscle fibers of the *Lonchura striata* and *Copsychus saularis* are significantly greater than the pectoral muscle fibers ($P < 0.01$), the density of male leg muscle fibers is significantly larger than that of the pectoral muscle fiber ($P < 0.01$), while the leg muscle fiber density is extremely smaller ($P < 0.01$) than the pectoral muscle fibers of *Lonchura striata* (Fig 1 to 3). In the univariate analysis of variance, differences are found in the characteristics of muscle fibers in two parts. There might be two factors causing such difference. Firstly, the life activities of the two parts are different. *Lonchura striata* and *Copsychus saularis* are both passerines and songbirds, good at flying. Pectoral muscles are usually involved in fly

activities which requires for stronger muscle fiber such as the red muscle. The red muscle fiber is thinner and the density is bigger than the common white muscle fiber (Torrella *et al.*, 1998). There are more red muscle fibers in pectoral muscle and the density of pectoral muscle fibers is greater than that of leg muscle fibers, which may prove its better. Secondly, hormone levels will pose different effects on the characteristics of muscle fibers in different parts (Bell *et al.*, 2000) and corresponding to different life activities. Therefore, it will also affect the characteristics of pectoral and leg muscle fibers.

Influence of gender on the histological characteristics of muscle fibers

The diameter and area of muscle fibers in males are larger than those in females in the same part of *Lonchura striata* and *Copsychus saularis*. However, male leg muscle density is lower than it in females, male pectoral muscle density is larger than that in females (Fig 3). The reasons may be related to two aspects: one refers to the different gender division of labor. Males need to undertake the tasks of foraging and defense with more flight activities (Huang *et al.*, 2020). On the other hand, the levels of sex hormones are different in different genders. Different sex leads to different secretion levels of sex hormone and this might cause different growth and development of skeletal muscle. Androgen can stimulate the growth of skeletal muscle and promote protein synthesis (Bell *et al.*, 2000). It is concluded that under certain feeding conditions, gender has a significant impact on the characteristics of muscle fibers. The density of male pectoral muscle fibers is higher and the characteristics of muscle fibers are better than females and the density of leg muscle fiber in females is higher than that in males.

Differences in histological characteristics of muscle fibers among different species

The diameter and area of pectoral muscle fibers in female *Copsychus saularis* are significantly larger than those in female *Lonchura striata* ($P < 0.01$) (Fig 1 and 2). The fiber density of leg muscle of *Lonchura striata* is less than that of *Copsychus saularis* and the fiber density of pectoral muscle

is greater than that of *Copsychus saularis* ($P < 0.01$) (Fig 3). The formation process of muscle fibers is complicated, but the development process of muscle fibers of different species is basically the same. However, there are differences among species in regulation of the muscle fiber development. Many core genes and protein families have significant regulatory effects on the composition, energy metabolism and quantity of muscle fibers (Sun *et al.*, 2019; Zhao *et al.*, 2020; Feng *et al.*, 2019). The muscle fiber difference between *Lonchura striata* and *Copsychus saularis* may result from different levels of gene regulation, which makes the characteristics of muscle fibers more adapted to the living habits of the corresponding species (Lv *et al.*, 2019; Lang *et al.*, 2020). There are differences in feeding habits and habits between the two birds. *Lonchura striata* belongs to herbivore and feeds on plant seeds, especially on rice (Huang *et al.*, 2020; Karasov, 1996) and *Copsychus saularis* mainly feeds on fruits and insects, with different food types due to seasons (Barnea *et al.*, 1991; Yuan and Yan, 2016). The difference in the characteristics of the muscle fibers of two birds may conform to the differences in the living habits.

Influence of species, gender and parts on muscle fiber characteristics

One way ANOVA is used to derive main and interactive effects for the three factors of the data. Main effects can be characterized at multiple levels when assessing one or more factors and assess the effect produced by a certain influence factor on the dependent variable. Data analysis results show that there are differences in the characteristics of muscle fibers among different species, genders and parts and there are interactions between any two factors. In the inter subjective effect test, the P values of species, gender and parts are all less than 0.05, therefore, all these three factors have significant impact on the density of muscle fibers. Among the interaction effects, the P values of the interaction effects between species and gender, species and parts and gender and parts are all less than 0.05, which means statistically significant. So, the effect of one of these three factors is affected by the level of the other two factors.

In the interactive effect of species and gender, the muscle fiber density of the two birds in the male is

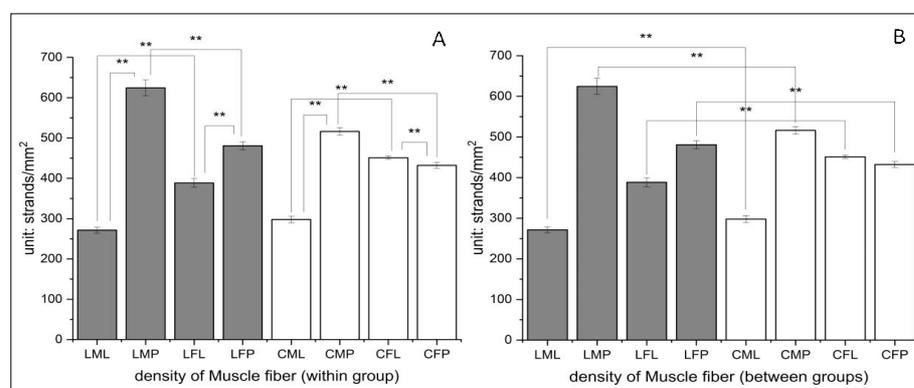

Fig 3: Comparison of muscle fiber density (root /mm²) A. Compared within group; B. Compared between groups.

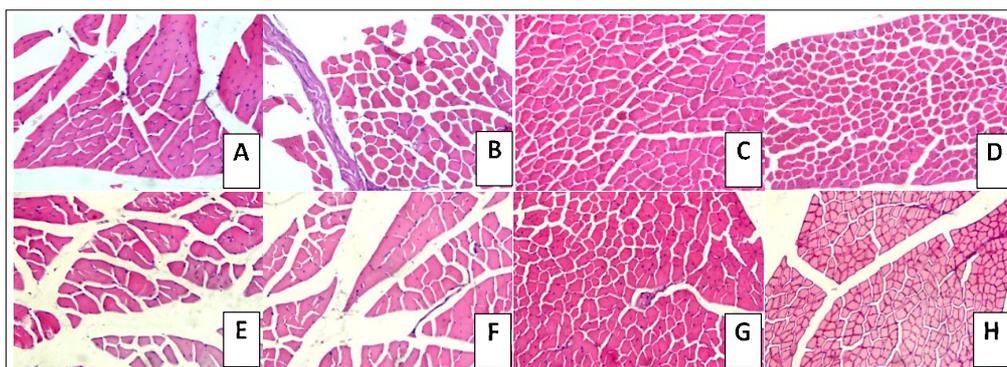

Fig 4: Muscle fiber microstructure of the leg muscle and pectoral muscle of *Lonchura striata* and *Copsychus saularis*.

A. *Lonchura striata* male leg muscle; B. *Lonchura striata* female leg muscle; C. *Lonchura striata* male pectoral muscle; D. *Lonchura striata* female thoracic muscle; E. *Copsychus saularis* male leg muscle; F. *Copsychus saularis* female leg muscle; G. *Copsychus saularis* male pectoral muscle; H. *Copsychus saularis* female pectoral muscle.

significantly different. The muscle fiber density of *Lonchura striata* males are larger ($P < 0.05$) than that in *Copsychus saularis* males, but there is no significant difference of this between the two female species ($P > 0.05$). The male and female differences between the same species of *Lonchura striata* and *Copsychus saularis* are significant ($P < 0.01$), but the density of muscle fibers in males of *Lonchura striata* is extremely greater than that of females ($P < 0.01$), while the density of muscle fibers in males of *Copsychus saularis* is significantly lower than that of females ($P < 0.01$), which may be related to the division of labor between male and female and the different hormone levels of the two species. Among the interactive effects of species and muscle fiber part, the density of leg and pectoral muscle fibers is significantly different between two bird species. The muscle fiber density of *Lonchura striata* leg muscle is smaller than that of *Copsychus saularis*, while the pectoral muscle fiber density is greater. Leg muscles and pectoral are significantly different in each bird. The density of the pectoral muscle is much better than that of the leg muscles and the density of the leg muscles and pectoral muscle are significantly different in *Lonchura striata*. In the interactive effects of gender and parts, the leg muscles and pectoral muscles between males and females are significantly different. The leg muscle fiber density of males is lower than that of females, while the pectoral muscle fiber density is greater than that of females. The differences between leg and pectoral muscle in different gender are significant (Fig 4).

In short, there are statistical differences between different species, genders and parts. The second-order interaction effects of the three factors of species, gender and part are statistically significant, while the third-order interaction effects are not statistically significant. It is suggested that all the three influencing factors of species, gender and part have a significant impact on the characteristics of muscle fibers. Meanwhile, each factor also has a certain influence on the effect of the other two factors.

CONCLUSION

The differences of species, gender and parts have a significant impact on the histological characteristics of muscle fibers and the effects of each influencing factor will be different depending on the different expression levels of the other two factors. The diameter, area and density of muscle fibers can be affected to various degrees, among which the density of muscle fibers is the most sensitive one. The results of this study provides a reference for the investigation of influencing factors of the histological properties in muscle fibers.
